

# Test verification and anomaly detection through configurable telemetry scanning

Alan S. Mazer

Instrument Flight Software Group  
Instruments Division  
Jet Propulsion Laboratory, California Institute of Technology

E-mail: [alan@judy.jpl.nasa.gov](mailto:alan@judy.jpl.nasa.gov)

- Despite hundreds of hours of testing (or more), flight software still launches with undiscovered errors
- By launch, software has passed through many hands
  - Developers
  - Peer reviewers
  - Integration and test (I&T)
  - ATLO pre-launch testing
- Sometimes, if not often, anomalous behavior is captured in test data unnoticed
  - GALEX
  - MICAS camera (Deep Space 1)

**The realities of software testing**

- Time constraints
  - Sometimes we barely have enough time to write the software
- Software developers aren't suited to testing
  - Testing is tedious
  - Engineers are limited by their "creator" perspective
- Independent testing is a thankless job
  - Learning curve costs time and money
  - Find problems and people are upset; don't find problems and people wonder why you're paid

**Why aren't problems found during development?**

- Time constraints
  - System I&T is usually pressed by schedule
- Errors may present subtly
  - Small telemetry oddity may reflect larger problem
- Cost constraints
  - Expertise to recognize software errors is not always present
- Trust
  - Test teams rely on developer testing, prioritizing software checkout below other pressing issues
  - Software problems can always be fixed “later”

**Why aren't problems found during instrument I&T?**

- “Human factors”
  - People get tired and make mistakes
  - Testers may not want to question what they’re seeing
  - People following procedures focus on following the steps rather than thinking about what they’re seeing
- Late changes
  - Without regression tests, late changes introduce risk as new requirements are implemented by developers who have already moved to other projects and forgotten the code

And...

- Phase B/C (pre-I&T)
  - Define scriptable tests to exercise code
  - Provide visibility into software operation through (perhaps optional) telemetry
  - Verify telemetry to determine whether or not test passed
- Phase D (I&T, ATLO)
  - With system engineering, create validity rules for all telemetry points, capturing expertise and determining which anomalies are reportable
  - Verify all test telemetry against rules

**What can we do about this?**

- Detailed telemetry verification is not well supported by common tools
- One approach to verifying a test is to compare test telemetry to previous runs
  - Simple
  - Works only if telemetry outputs don't vary from run to run (e.g., due to harmless timing variations)
- Another is to use Unix *expect* (a selective *diff*) to verify critical outputs
  - Can ignore innocuous variations in telemetry
  - But...
    - All telemetry must be converted to ASCII
    - Repetitive goals are tedious to set up
    - Doesn't support all-telemetry checks

**Verifying telemetry is still hard**

- Decided to create a rule-based parser, HKCheck, based on ASCII user-authored configuration files
  - Post-processes binary data streams
  - “Protocol” spec describes packet/message format(s)
  - “Test” spec describes constraints on each telemetry point, and user goals to be satisfied by a particular test
- Supports phase B/C test verification by checking for test goals in telemetry
  - A goal might be an intended error or receipt of a particular command
- Supports phase B/C/D by scanning telemetry and calling out unexpected values

**Wrote HKCheck to parse telemetry**

- “Protocol” spec
  - Supports heterogeneous packet streams, matched to packet definitions at run-time based on packet contents
    - For example, engineering and science packets in a common stream
    - Packets may be variable-length
  - Provides about a dozen built-in data types
    - Integer, floating- and fixed-point values
    - Various time types, with a variety of epochs
    - Several byte orderings
  - Allows user-defined constants and data types, and arrays
  - Display formats are specific to each telemetry point

**“Protocol” defines packet formats**

```
consttable packetType = {  
    NOMINAL = 0  
    DUMP = 1  
}
```

User-defined  
constants

```
packet sciencePacket = {  
    uint8:packetType    PacketType  
    uint16:dec          PacketNumber  
    uint8:hex           Status  
    time4s4ss:date     SpacecraftTime  
    uint8:hex           ScienceData[200]  
} if (PacketType == NOMINAL)
```

Packet def

```
packet dumpPacket = {  
    uint8:packetType    PacketType  
    uint8:dec           DumpLength  
    uint8:hex           DumpData[DumpLength]  
} if (PacketType == DUMP)
```

Packet def

- Each packet def lists a sequence of telemetry points contained in that packet type.
- Each telemetry point has a data type (e.g., uint8), a display format (e.g., date, hex), and a name

## Simple Protocol Definition

```
datatype error = {  
  uint8:errorID      errorID  
  uint8:hex          details[5]  
  time4s2ss:date     errorTime  
}  
  
datatype downloadCommand = {  
  uint16:hex  memoryAddr  
  uint16:dec  bytecount  
}
```

“Error” data defines structure of single telemetry point for display

- User-defined data types allow multiple telemetry points to be grouped as one
- Reduces complexity of packet definitions
- Simplifies output displays (e.g., error description is one line rather than 3)

## Simple User-defined Types

```
subpacket status = {
  uint16:dec      PktCnt
  uint8:hex       FswVer
  uint8:hex       ScienceVer
  uint8:hex       SensorVer
  uint16:hex      Status
  uint8:hex       Mode
  time4s2ss:dec  SCTime
  uint16:hex      CRC
  uint8:dec       Resets
  uint8:dec       TimesMiss
  uint16:dec      CmdsRcvd
  uint16:dec      CmdsExec
  uint16:dec      CmdsRejected
  mwrMessage      LastMsg
  mwrError         LastErr
  uint16:dec      ErrorCount
}
```

“Status” subpacket groups status items which appear in both science and engineering packet formats

- Subpackets group related telemetry items for inclusion across multiple packet definitions

## Subpackets

```
set byteorder=msb4thin8
```

```
subpacket header = {  
  uint16:hex  
  uint16:dec  
  uint16:dec  
  uint16:hex  
  uint16:hex  
}
```

```
syncWord  
msgID  
wordCount  
flags  
checksum
```

Middle-endian byte ordering specified

All packet formats include common header

```
packet timemarkPacket = {  
  subpacket  
  fixed<1+20+43>:hms  
  fixed<1+17+46>:hms  
  uint16:none  
  uint16:dec  
  uint16:dec  
  uint16:dec  
  uint16:hex  
} if (msgID == 3623)  
  header  
  gpsSecs  
  utcSecs  
  pad[5]  
  day  
  month  
  year  
  data[wordCount-15]
```

Format of GPS TimeMark packet

```
packet allOthersPacket = {  
  subpacket  
  fixed<1+20+43>:hms  
  uint16:hex  
} header  
  gpsSecs  
  data[wordCount-3]
```

Format of other packets

# Protocol for GPS/IMU Data Stream

- Typical protocols for flight instruments run to hundreds of lines
  - User-defined data types and constants
  - Subpacket definitions
  - Multiple packet definitions

**Real-life Protocols Are Large**

- “Test” spec contains actions for each telemetry point to be performed on each applicable packet
  - Allows each telemetry point to be verified against user-defined conditions and/or conditionally displayed
  - Error and display conditions...
    - Use C-like syntax
    - Can reference the current, previous, and last-different values
    - Can reference the age (in packets) of the current value

**“Test” defines conditions for each telemetry point**

- For this example, want to...
  - Verify packet numbers are sequential
  - Verify that S/C time in each science packet is later than previous S/C time, but not by more than 5 seconds
  - Display the contents of each non-empty dump packet
- Nomenclature:
  - \$ refers to current value; \_\$ is last value
  - "template", "check", and "show if" are keywords

```
template mytest = {  
    PacketNumber          check $ == _$+1  
    SpacecraftTime        check $ > _$ && $ <= _$+5  
    DumpLength            show if $ != 0  
    DumpData[0..254]      show if DumpLength != 0  
}
```

## Simple Test Actions

- “Test” files may specify sequential goals to be met
  - Can be used to verify that a test completed successfully as reflected in telemetry
  - Goals are simply conditions using same syntax as used for checks

**“Test” file defines optional goals to satisfy**

- For this example, want to...
  - Verify that first packet in stream is science packet
  - Verify that we have at least one non-empty dump packet
- Nomenclature:
  - “goal” is a keyword

goal “First packet is science packet”  
(PacketNumber == 1 && PacketType == NOMINAL)

goal “Found dump”  
(PacketType == DUMP && DumpLength != 0)

## Simple Test Goals

- HKCheck takes the protocol and test file(s), along with the binary telemetry input, and generates a report
- Reports show
  - Rules violated ("check")
  - Conditionally-displayed values ("show if")
  - Goals met and unmet ("goal")
  - Summary notes ("startnote" and "endnote")

**Output**

- In this portion of a run on flight telemetry from Mars Climate Sounder, HKCheck found an odd time increment (nominal is 2-3 seconds)
- Nomenclature:
  - “start” is a keyword which evaluates true the first time a packet type appears in the stream

SCTim has an error value: 887581376 (was 887581375)

Requirement:

```
start || Resets == _Resets+1 ||  
($ >= _$+2 && $ <= _$+3)
```

## Output Example

LastCmd UPLOAD XRAM 0xcee7 138 0x80 0x75 0x2d

LastCmd UPLOAD XRAM 0xdd46 8 0x02 0xc6 0x77

LastCmd UPLOAD XRAM 0xde84 8 0x02 0xc6 0x30

LastCmd EQX 0 250

Met goal: "CRC check"

Met goal: "Pos-error resync #1"

Met goal: "Pos-error resync #2"

Met goal: "Pos-error resync #3"

...

Status has an error value: 0x42 (was 0x02)

Requirement:

\$ == 0x00 || \$ == 0x02 || \$ == 0x40

Met goal: "Pos-error resync #4"

EOF

All goals met

Failed -- found one or more errors

## Another Output Example

- Useful for ASCII-fying telemetry through “show” statements as a test record
- Optionally generates spreadsheets as .csv files, or native Excel (with commercial add-on package)

## Miscellaneous Capabilities

- Enables rapid, repeatable testing during development
- Post-launch telemetry can be scanned...
  - to confirm instrument health
  - postmortem, to look for odd conditions prior to a failure
- Allows expertise to be encoded in rules, reviewed, and carried through the life of the project
- Used for flight software regression testing or telemetry scanning on
  - Mars Climate Sounder (MRO), Diviner (LRO), Microwave Radiometer (Juno), Phoenix MECA, GALEX, and various airborne missions
- Open-source release pending

## Summary
